AN INTRODUCTION TO PROFESSIONAL EMERGENCY COMMUNICATIONS PREPAREDNESS
INTRODUCTION TO RADIO RELAY INTERNATIONAL

• International in scope
• Universal methods
• Technologically advanced
• Survivable
• Decentralized
• Flexible
HISTORY OF RRI

• Founded in 2016
• Created out of the assets of the old “National Traffic System”
• Dedicated solely to emergency communications preparedness
• Organic in nature. Management selected by election.
• Professional standards
RRI CORPORATE STRUCTURE

• An IRS 501(c)(3) registered nonprofit organization.
• Registered in the State of California as a public benefit corporation.
• Dedicated solely to the development of International emergency communications.
• E-mail reflector for discussion and distribution of news bulletins, etc.
• **Quarterly Journal:** “QNI-The Traffic Newsletter:” www.qni-newsletter.net”
SOME FUNDAMENTALS OF EMERGENCY COMMUNICATIONS:

Four vital characteristics are considered in order of importance:

• Survivability
• Flexibility
• Circuit Capacity
• Security
SURVIVABILITY

• “When all else fails”

• By definition, disasters are catastrophic

• The Amateur Radio Service is not needed unless damage is sufficient to destroy or disrupt commercial and/or government infrastructure.

• Survivability is therefore the FIRST and foremost responsibility of any emergency communications organization.

• Survivable networks facilitate the restoration of networks of greater flexibility or circuit capacity.

• Achieved through simplicity (e.g. HF radio) or redundancy (e.g. PSTN)
FLEXIBILITY

• A communications system is of little value unless it can be deployed where needed.

• Open architecture and network topology are essential to improvisation in time of emergency.

• Beneficial characteristics include; portability, frequency agility, universal common denominator modes.

• Each emergency response function has unique requirements. Therefore, some modes are better suited to certain emergency response functions.

A diversity of modes is essential to an effective emergency communications system.
CIRCUIT CAPACITY

- Occasionally mistakenly referred to as “bandwidth.”
- Quantity of message traffic that can be conveyed in a given time period.
- **Survivability** and **flexibility** are more important than circuit capacity.
- *It matters not that one can send 100 encyclopedias per minute if it can’t be done from where it is needed.*
- *Large quantities of message traffic can be detrimental to the rather slow “human” decision-making process.*
SECURITY

Two types:

1. Inherent (natural)
   - Frequency management
   - Mode specialization
   - Radiotelegraphy, VHF/UHF SSB and digital modes

2. Designed
   - Encoding
   - Encryption (prohibited on Amateur Radio Service frequencies)

Communications security is usually of minimal concern outside of the military or national security environment. Inherent (natural) security is typically sufficient to avoid casual or media scrutiny
The Emergency Communications Pyramid

- SURVIVABILITY
- FLEXIBILITY
- CIRCUIT CAPACITY
- SECURITY
MODE SELECTION

Criteria for mode selection includes:

- Universality (common denominators)
- Efficiency (particularly in the High Frequency Spectrum (3-30 mHz)).
- Suitability to emergency function based on the four basic characteristics.

Examples:

- Voice methods in a patrol car.
- Data communications between an EOC and Incident Command Post.
- HF Radiotelegraph under poor propagation conditions.
RADIOTELEGRAPH

• Narrow bandwidth – More “efficiency per watt.”

• Ideal for operation using long-term renewable energy resources.

• Simple equipment is ideal for field operations, particularly in hostile environments (heat, sandstorms, monsoons, hurricanes, etc.)

“CW” is a universal common denominator – every transmitter/receiver manufactured since the 1920s is CW capable.
CW AND “CASCADIA RISING”

• Major Federal exercise in which RRI members provided connectivity between Alaska, Northern California, Oregon, Utah, Washington State and the FEMA National Response Coordinating Center (NRCC) in the District of Columbia:

  • CW 99.998 percent accurate against five letter cipher groups.
  • CW proved faster than automated digital modes.
  • CW proved more reliable than automated digital modes.
  • Message propagation time from origination to delivery at NRCC in 10 to 15 minute range.

*Is CW obsolete? You be the judge.*
CW AND Y2K ROLLOVER

During Y2K event, CW was one of several government and Amateur Radio modes used to provide hourly updates from EOCs, State Police Posts, Prisons and Prison Camps throughout Michigan.

- CW cleared traffic at a rate of 3.75 to 1 over voice methods.
- CW cleared traffic over digital (VHF packet) at a rate of 4 to 1.

Is CW obsolete? You be the judge.

Note: Data determined by independent third-party analysis.
VOICE METHODS (SSB, FM, ETC.)

• Large operator pool

• *Universal common denominator* - Nearly any HF radio manufactured since the mid 1960s is capable of HF-SSB communications.

• Retention of basic VHF-FM repeater infrastructure supports mutual aid and interchange of operators/volunteers *throughout North America*.

• Basic radiotelephone skills can be easily developed.

“Have radio will travel.”
DIGITAL METHODS

• Some digital modes offer narrow bandwidth and excellent propagation resistance.

• Some incorporate automatic error correction (except for the “human interface”).

• Capability to convey binary files (documents, photos, spreadsheets, etc.).

• Require additional equipment (laptop, tablet, modem, cables, etc.).

• Additional failure points.

• Value diminishes in the emergency operations environment unless there is access to a printer so hard-copy messages can be delivered.
RRI DIGITAL TRAFFIC NETWORK

• International network infrastructure utilizing PACTOR-3 and BPQ-32 Software Platform.

• PACTOR-3 backward compatible to PACTOR-1.

• PACTOR affords:
  • Complete automation
  • Error correction
  • Propagation resilience

The RRI “Digital Traffic Network” uses a hybrid mesh, all-RF network topology ideally suited to infrastructure purposes.
OTHER DIGITAL MODES

• Local and state (“section”) emergency communications units and traffic organizations are at liberty to build networks around other digital modes.

• The RRI Digital Traffic Network (DTN) supports any digital (or manual) mode network via the “Digital Traffic Station” (DTS) interface/liaison function.

• Standardization is essential at higher levels to facilitate universal interfacing and the automatic routing of message traffic.

Standardization is essential to support mutual aid and interoperability. Emergency communications organizations operating at the local and state level should consider the impact of mode and software selection on mutual aid and interoperability.
DIGITAL TRAFFIC STATION (DTS)

• A properly trained operator or station equipped with PACTOR-1 or greater equipment.

• Registered with the RRI and authorized to access the DTN layer.

• Responsible for providing interface between manual mode common denominator (voice/CW) networks or unique digital mode networks and the Radio Relay International DTN infrastructure.

• May be associated with an EMCOMM group, traffic net, agency or NCERT.
DIGITAL TRAFFIC NET EQUIPMENT BANK

• Basic PACTOR-1 modems loaned to DTS appointees.
• RRI retains ownership of modems.
• Modem to be returned if DTS resigns.
• Program intended to rapidly expand DTN operations.
NCERT – “NATIONAL COMMUNICATIONS EMERGENCY RESPONSE TEAM”

- A team of self-sufficient, properly trained operators equipped with:
  - PACTOR for DTN access – Team registered as DTS
  - PACTOR for WL2K access
  - Radiotelegraph
  - Radiotelephone
  - VHF and UHF-FM
  - Other modes pertinent to local EMCOMM environment within service area

NCERT is NOT a substitute for local emergency communications programs. Rather, it is a team of specialists responsible for supporting major agencies or dedicated to providing specialized communications functions in support of local operations.
MANUAL MODE NET STRUCTURE

• Facilitates common-denominator (universal) access – Larger pool of operators.

• Provides hands-on training in the management of third party traffic.

• Proven reliability.

• Greater flexibility than digital infrastructure:
  • Point-to-point circuits
  • Special Routings
  • Superior “last mile” connectivity.
  • Ability to respond organically to unpredictable emergency communications problems.

*Manual mode nets offer camaraderie, an operating challenge, and universality.*
RRI Central Network topography showing Cycle 4 traffic flow and temporal relationship between manual mode net sessions.

Outgoing routine traffic originates at state level at 0100Z.

Incoming routine traffic posted at state level for routing to delivery at 0400Z.

State (section) net times approximate.
Region Net Covers Multiple States (Region 10)
Area Nets Cover Western, Central and Eastern Areas of North America.
INTER-AREA TRAFFIC NETWORK (IATN)

• Specialized circuits facilitate the exchange of message traffic between Area Networks.

• Radiotelephone (day) and Radiotelegraph (night).

• CW proven to be the most reliable method, particularly under poor propagation conditions.

• Capable of specialized configuration using a National Communications Response Plan to speed traffic throughput.
Inter-Area Traffic Network (IATN) point-to-point circuits linking manual mode networks. Note Cycle 2 (daytime) and Cycle 4 (nighttime). Additional cycles and specialized QSX frequencies can be added to facilitate 24-hour operations.
DIGITAL TRAFFIC NETWORK

• Infrastructure operates primarily at region, area and International level.
• Interface between state (section) and local manual mode nets via DTS.
• DTN gateways optional (encouraged) at local/state level.
• DTN gateways optional (encouraged) at served agency facilities.
• A VHF/UHF DTN gateway is an ideal addition to an ARES® or AUXCOMM county or municipal unit.
DTN Topography showing modified mesh network. Gateways may be established locally on VHF/UHF. Manual mode networks interface via the DTS function.
EMERGENCY OPERATIONS

Radio Relay International utilizes two network configurations:

• **Routine**: Daily operations time sequenced to route routine message traffic. This configuration is designed to route routine radiograms in a few hours.

• **Emergency**: Networks configured to clear message traffic ASAP. Manual mode nets utilize special routings and network configuration as defined in *National Communications Emergency Response Plan*. DTN configured to target served area(s).
NATIONAL RESPONSE PLAN - NRP

• Mode/Frequency Matrix specifies frequencies for manual modes.

• Mode/Frequency Matrix specifies region and area DTN hubs with scan frequencies.

• Specific state(s) or section(s) defined as targets for message routing and delivery to served agencies.

• Network Management Coordinator assigned to collect data identifying participating stations, their capabilities, connectivity to specific agencies/NGOs and their operational status.

• Message content can be defined for specific functions.
ACCOUNTABILITY AND NETWORK MANAGEMENT

• Who is responsible for the content of the message and what is his authority?
• When was the content of the message drafted and presented for origination?
• Has the content of the message been superseded by subsequent message traffic?
• What operator/station and network has access to the signatory?
• How important is the message to the originator?

_In many cases, it is not sufficient to simply “talk” a message into a microphone._
RADIOGRAM FORMAT

• Defines network topology.

• Assigns accountability.

• Defines temporal context (sequence of message traffic).

• Identifies messages in a large file to facilitate service messages and ease of reference in replies.

• Ensures message remains intact through last mile (message integrity).

• Facilitates automation within automated digital networks.
ORIGINS OF RADIOGRAM FORMAT

• Origins in commercial telegraph practice.
• Analogues in message formats used by Western Union, Postal Telegraph, Radiomarine Corporation (RCA), MacKay Radio, military methods, etc.
• Network management data is similar to the modern e-mail.
• NOT created by the ARRL, but rather, imported from other services.
ICS213 VS. RADIOGRAM

• The ICS213 is a minimum standard designed only for accountability ONLY – “Interoffice Memo.”

• The ICS213 is suitable only for local functions.

• Radiogram incorporates additional network management data to ensure message integrity during transfer between multiple networks/services.

• Radiogram facilitates service messages reporting errors.

• Radiogram defines network topology to ensure that reply messages can be directed to the operator/station/network having access to the proper official.

• ICS213 can be conveyed in a radiogram wrapper.

The Federal Emergency Management Agency has accepted operational message traffic in radiogram format during major national exercises.
RADIOGRAM COMPONENTS

The Preamble includes service data and address.

Message No. – Serial number assigned by originating station. Allows one to quickly locate a message in a large file during emergency operations within an EOC or similar facility. The serial number should be kept small to facilitate interoperability between modes.

RADIOGRAM COMPONENTS (CONT.)

**Precedence:** Defines the importance of the message to the individual or agency whose signature is associated with the message.

- **Routine:** Message of general interest.
- **Welfare:** Message pertaining to the wellbeing of an individual in a disaster area.
- **Priority:** Message that is time-sensitive in nature, including official agency traffic.
- **EMERGENCY:** Life critical (vital) message related to the immediate safety or life of individual(s).
- “Test” (“T”) placed before the precedence in exercise messages.

Handling Instructions (HX) – Optional

• Specifies actions to be taken by either the delivering operator or those handling the message within the network.

• “HXA through HXG”

• See RRI Operating Manual for more details.

Example: HXC: Report time and date of delivery to originating station.

Station of Origin:

• Identifies operator/station having access to official/agency whose signature is associated with the radiogram, thereby facilitating the routing of replies.

• Essential network management data.

• The first station of to inject the message into the network.

If W8ABC calls W8XYZ on the phone and asks him to send a message on his behalf, the station of origin is W8XYZ, NOT W8ABC.

RADIOGRAM ICS213 MESSAGES

• Radiogram format contains all of the essential information required by the ICS213 standard.

• Transcribing a radiogram onto an ICS213 message form is simple.

• Radiogram format adds additional network management data not included in the ICS213 standard.

• Network management data is essential to an effective EMCOMM messaging layer.
Network Management Data - Preamble

- Preamble in same position as standard radiogram.
- Administrative data identifies network topology, routing and point-of-contact for signatory and temporal relationship to related messages.
- Exceeds minimum requirements of NIMS ICS213 standard – a better quality of service.
- Consistent with routine traffic thereby leveraging maximum training benefit from regular traffic handling activities.
Address Component – Same as standard radiogram

- Address should include agency and title (if applicable).
- Complete address preferred unless absolutely certain receiving station has direct access to addressee.
- Phone and/or e-mail.
- If delivering via e-mail, be certain to inform addressee using alternate communications method (with feedback) of the need to check his/her in-box.
Signature Block – Same as standard radiogram

- Signature block is moved ahead of text to conform with typical ICS213 generic forms.
- May be necessary to transcribe text in area below FIRST, then return to this block to transcribe radiogram signature.
- Same requirements as standard radiogram format.
### Radiogram ICS-213 Message

**To (Name):**

**LT FRANK J NAVIN**

**Position (Title & Agency):**

**MICHIGAN STATE POLICE EMD**

5512 CANAL ST

**City, State, Zip:** LANSING MI 48234

**Telephone and optional e-mail:** 517 555 2323

**From (Name):**

**DR MILLARD BASS**

**Position (Title & Agency):** DETROIT MEDICAL EXAMINER

**Agency Local Time (conversion from UTC):** 2103 EDT

**Routing Data:**

- TEMPORARY MORGUE ESTABLISHED AT CLEVELAND INTERMEDIATE SCHOOL, 13322 CONANT STREET, HAMTRAMCK 48212

---

**Text Block – same as standard radiogram:**

- Transcribe five or ten words to a line (with extra space between groups of five) to facilitate rapid group count.
- Transcribe all-capitals to facilitate interoperability and indicate to addressee that message text is case insensitive.
- Spell scientific abbreviations (e.g. “milligrams” instead of “mg”)

**Routing Data - same as standard radiogram:**

- Retain for tracking lost messages.
- Further defines network topology.
- Limits liability of radio operator.
EMERGENCY SUPPORT

RRI Supports two types of emergency response:

• *Organizational Response*: Infrastructure for local and state EMCOMM organizations, Federal agencies and relief organizations.

• *Individual Response*: Infrastructure for *individual* radio amateurs providing basic communications for their neighborhood, CERT organization, SAR team, etc.

*RRI and related traffic nets provide an excellent “ready-made” infrastructure for small EMCOMM groups and individual radio amateurs.*
HOW TO GET INVOLVED:

• The best way: Listen to nets, follow procedures.

• Read the RRI Training Manual TR-001 and the RRI Field Manual FM-001.

• Register with RRI (Radio Operator Registration Form 1601).

• Read back issues of the QNI Newsletter (www.qni-newsletter.net).

• Integrate routine traffic handling into weekly, local EMCOMM nets.

• Originate routine messages to family, friends, fellow radio amateurs.
AVOID “DISUSE ATROPHY”

• Radio amateurs can “play” and experiment because they also provide a public service.

• Use Amateur Radio Service facilities instead of commercial facilities for administrative activities, “radiogram QSLs,” to arrange schedules, etc.

• Excessive use of commercial systems to handle basic Amateur Radio Service business undermines our own capabilities and leads to “disuse atrophy.”
Myth: “Emergency Traffic (welfare, priority or emergency) must be forced through the entire network.” Truth: Special procedures facilitate rapid routing or delivery.

Myth: “Delays of routine message traffic is a network design fault.” Truth: Routine traffic delivery delays are typically the result of a volunteer deficiency (no outlet).

Myth: “Traffic networks are slow.” Truth: Traffic flows quickly through infrastructure as proven during recent major disasters.

Most delivery delays to routine traffic are due to a lack of volunteers in the destination area. Under emergency conditions, traffic can be placed on special circuits or taken off of the system at the first available delivery point.
WHY EXERCISE THE ENTIRE SYSTEM?

Routine message traffic is moved through the *entire* system from point of origin to point of delivery for the following reasons:

• Provides maximum training benefit across the system.
• Keeps nets at all levels active and “well-oiled.”
• *Ensures operational readiness.*
• Social dynamic – camaraderie, fun, sense of purpose.
WHY HANDLE TRAFFIC?

• The simple answer: It’s **fun and beneficial**.

• If one can accurately handle routine messages, he is better equipped to handle important served agency messages in time of emergency.

• Traffic work and emergency communications operations requires that one have the ability to communicate at a **given time**, on **specific frequencies** and **over specific coverage areas** regardless of RF propagation conditions. *This is far more demanding than contesting or casual operating in which one simply communicates with points that existing RF propagation favors.*
